

END-TO-END REPORT • JEV 1.13 • TYPESAFE.AI • SEP 19, 2026

Jev.

The first (public) System One model — and the strange new way it is powering AI agents.

not chat decisions, not strings calibrated confidence 70-500 ms output tokens: free zero hallucinations*

ChatGPT broke Diogo Almeida's heart.

That's how [TechCrunch](#) opened its profile of the founder — and it's the whole thesis in one line. Almeida was an OpenAI researcher who helped build ChatGPT and co-invented RLHF, the training technique behind the entire chat era. His verdict on the result: *"We have lightning in a bottle, and yet it is not useful."*

His diagnosis: we spent four years optimizing models for **human language**, but automation runs on a different language. Computers need typed values they can branch on — not prose they must parse, validate, and second-guess. RLHF made models superhuman at pleasing people; it also made them overconfident, inconsistent, and dependent on humans-in-the-loop.

So TypeSafe took the opposite research direction: stop optimizing for human preference and start optimizing for **calibrated decisions** that software can act on directly. After two years in stealth, the company emerged on September 15, 2026 with a new architecture, a parallel sampler, and a new training algorithm — **RLCD, Reinforcement Learning for Calibrated Decisions** — and its first model: **Jev**.

"Think of Jev as a frontier-intelligence function call: unstructured state in, typed probabilistic decisions out."
— Diogo Almeida, founder, TypeSafe (launch post)

timeline

2022-24

· Almeida's OpenAI work ends up as research behind ChatGPT + RLHF

2024

· leaves OpenAI: "optimizing for human language is the bug"

2 yrs stealth

· new architecture + parallel sampler + RLCD; trained exclusively on synthetic data – "better bet than RLHF"

Sep 15, 2026

· launch: blog post + X announcement + HN

Sep 15

· "we briefly lost the ability to serve users from our API because demand was so high" (TechCrunch)

Sep 16-18

· ecosystem explosion: 5,300+ repos, TechCrunch profile, Venice API, OpenRouter listing

Names: "System One" from Kahneman's *Thinking, Fast and Slow* — fast intuitive judgment vs slow deliberate reasoning. "Jev" from William Stanley Jevons: as the cost of a resource collapses, demand explodes — the thesis that cheaper intelligence means *more* software intelligence everywhere, "much more like the early internet" (Almeida).

A frontier-intelligence function call.

An LLM generates one token at a time, each conditioned on the last. Jev does no autoregression at all: it reads a **state**, and answers all your **typed questions** in a single parallel pass — probability distributions, not text.

Noul

yes/no → probability, calibrated

Choice

one option from a set → distribution

Score

graded level on your scale → score + confidence

1 pass

all questions answered in parallel, same request

	EXISTING LLMS	SYSTEM ONE + JEV
Trained with	RLHF / RLVR — preference + verifiable rewards	RLCD — Reinforcement Learning for Calibrated Decisions
Outputs	Strings — parse + validate; hallucinations possible	Type-safe values defined in advance; type errors are mathematically impossible
Sampling	Sequential token-by-token	Parallel — all outputs in one query
Confidence	Overconfident, inconsistent	Every answer ships with calibrated probability + confidence
End-to-end	3–329 s (frontier)	70–500 ms

Source: typesafe.ai launch post + docs.typesafe.ai/concepts/system-one. Up to 255 options per choice; higher cardinality uses a two-stage score-then-choose. Trained on synthetic data only.

the wire (real)

```
// one HTTP request: state in, decisions out
POST /v1/systemone
{
  "model": "jev-latest",
  "state": { "ticket": "...", "customer": "..." },
  "questions": {
    "urgent": { "type": "noul",
      "instructions": "Is this a refund request?" },
    "team": { "type": "choice",
      "criteria": { "billing": "...", "technical": "...", "account": "..." } },
    "anger": { "type": "score",
      "criteria": [ "calm", "frustrated", "very frustrated" ] } }
  }
→ answers.urgent.noul = 0.95
→ answers.team.choice = "billing" + distribution
→ answers.anger.score = 1.4 + confidence
```

You declare the answer space, Jev fills in the probabilities; your code keeps the if-statements — act on high confidence, escalate low.

THE NUMBERS • RECEIPTS INCLUDED

193.6x faster. 444.6x cheaper.

Those are TypeSafe's own headline figures from its workflow evals — and the company openly calls them "on the higher end of real world gains." The verifiable floor: every call is 70–500 ms, input is **\$0.042 per million tokens (\$42 per billion)**, and output tokens are effectively **free** — "too cheap to meter."

193.6x

faster on workflow evals (headline, their fig.)

444.6x

cheaper on workflow evals (headline, their fig.)

\$42

per billion input tokens

238x

cheaper input than Claude Fable 5.1

∴ the workflow evals (a new kind of benchmark)

Instead of pass/fail Q&A, TypeSafe built evaluations where a real automation task is decomposed into code: deterministic rules + narrow typed questions. Every model runs the *same harness*; reference answers are the average of GPT-6 Astra and Claude Fable 5.1 at high thinking. Result: **Jev owns the Pareto frontier for almost two orders of magnitude** — nothing is both cheaper-and-more-accurate or faster-and-more-accurate.

The four published workflows: **security incidents** (close / escalate / contain), **agent-trace observability** (does a human need to review?), **invoice processing** (pay / hold / return), and **customer service** (what should the agent do next). Averaged across all four, *every* model scored better inside the workflow than as a one-shot prompt — structure itself is the win.

TypeSafe discloses its own biases: evals written by its capabilities team, reference answers biased toward OpenAI/Anthropic models, and pricing that "could be subsidized." Full receipts at evals.typesafe.ai.

Workflow evals — mean accuracy vs cost & time, 4 tasks; Jev alone on the frontier. Measured run: \$0.000081 / 0.114 s vs \$0.01388 / 8.566 s.

THE CLAIMS, STRESS-TESTED • ZERO HALLUCINATIONS*

Can't hallucinate — but can still be wrong.

Hallucinated/invalid tool-call rates: LLMs leak; Jev is 0% by construction — the output space is defined in advance, so schema violations are mathematically impossible. (typesafe.ai)

the asterisk, honestly

- bounded output space prevents **invented answers**, not wrong-but-valid choices
- calibration is **group-level**: 0.90 ≈ 90% accurate in that band, no per-answer guarantee
- Jev gives up strings entirely — it cannot write text, reason step-by-step, or be your chat model
- architecture is closed; outside observers suspect an open-weight LLM base (TechCrunch)

The team is unusually candid — the launch post is titled around "receipts" and self-discloses demo caveats (the Doom bot is weaker than a scripted bot; wikiracing speedups shrink vs non-reasoning LLMs; the demo query "paints our model in an advantageous light"). Even the company's own head of devrel posted the limits plainly:

"Jev isn't perfect. We think it's still too slow, too expensive, and too dumb."
— Sasha Sheng (@hackgooler), TypeSafe — "Let us know how Jev is bad!"

Armin Ronacher (Flask creator, CTO of Earendil — makers of the Pi agent harness) framed the operational bargain best:

"It delegates the hallucination problem a little bit to the user. If this comes back with 50% probability, maybe it's a coin toss. But if it's 95% — sure, then I can do something with it."
— TechCrunch, Sep 18, 2026

That confidence ladder is the real product: **act when confident, escalate when not** — thresholds set by your code, not by the model's vibes. In practice teams pair Jev with a big LLM: macro reasoning to the LLM, high-frequency micro verdicts to Jev. Skeptic Armin again: competitors "should have seen this earlier... you often don't have to be creative yet" because LLMs are cheap and subsidized.

"Jev evaluates, code executes"

Four days after launch, GitHub listed 5,300+ repos matching "jev". A community radar cataloged **134 projects across 17 categories** — every one built on the same split: the big model plans, **Jev makes the high-frequency decisions, code executes them.**

Distribution of the 134 cataloged community projects (awesome-jev-projects radar dataset, Sep 18, 2026; categories merged where overlapping).

browser agent · 6.4K stars

jev-ultrafast

browser-use's "i. am. speed." agent: Jev picks every click/scroll/type in one 300 ms request per cycle; a small LLM only writes text. Google Flights task in 7.1 s.

agent memory · 3.7K stars

fast-jev-compaction

Claude Code plugin that kills lossy summarization: Jev scores every old tool call keep-vs-drop, keeping the ledger verbatim. Live session: 39% context reduction, ~300 ms.

guardrails · 729 stars

reticle

"Agents can generate code, but struggle to understand what they build." Jev gates whether completed work satisfies the stated requirements before it may claim done.

trading · 984 stars

jev-trader

One AI trade decision every Monad block — Jev on the Kuru MON-USDC pair. The speed ceiling is the chain, not the model.

open replica · 926 stars

jevlike

"Reverse-engineered Jev-like model" — hit HN front page (162 pts) within a day of launch; NanoJev (587 stars) trains a nano version end-to-end.

the pattern

Where Jev slots in

routing & cost (JevRouter), moderation bots, injection screening (jev-mcp verify/screen/find), trading, home automation (HA-Jev), Mario from emulator state, code review dashboards, semantic ifs on a 3090 (SemIf, 1.7K stars).

Platform wave: OpenRouter, Venice (beta), Vercel AI Gateway and Cloudflare Workers AI list the model; official skills reach Claude Code and Codex; MCP servers wire it into desktop agents. [All 134 projects → companion artifact](#)

Where the intelligence-per-dollar pays.

The official framing: Jev is for **AI-powered workflows** — **fuzzy if-statements** where hand-written rules are too brittle: classify, route, score, extract, branch; map-reduce over big data; real-time UX; and verifying other LLMs.

🔗 proven in production

WHO	USE CASE	RESULT
Vercel	Safety classifier for agent commands, replacing GPT-5.6 Luna	5–18× faster, more accurate
Bryo AI	1,565 business emails, 10 categories, vs Gemini	10–20× cheaper; "hands back a real probability"
This agent	Context compaction on old tool calls, via OpenRouter	298 ms · 39% context cut
Doom bot	Plays Doom from structured game state	~10 decisions/sec ≈ \$7/hr
Wikiracing	Wikipedia link-by-link to a target page	fewer steps than frontier LLMs

Sources: TechCrunch Sep 18 (Vercel eng. Pranit Sharma; Bryo CTO nikhilmudholkar); developer threads @fazxes, @nikhilmudholkar; typesafe.ai; this report's own agent runs Jev 1.13 via OpenRouter in production.

🔗 the four published workflows

security

Security incidents

Alert fires on a laptop/server → decide close, pass to analyst, or contain now, given everything on file about the machine.

agents

Agent-trace observability

After a support agent finishes a run (every tool call included) → does a person need to review it, and how soon?

finance

Invoice processing

Vendor bill + order + delivery evidence → pay, hold, or send back. Deterministic checks in code, judgments to Jev.

support

Customer service

Given the thread and account state → what the assistant should say and do next; frustration scoring along the way.

🔗 benefits, distilled

40–200× faster end-to-end

output tokens free → map-reduce petabytes

calibrated act/escalate ladder

no parse/validate layer

consistent on similar inputs

composes with code like a function

verifies & guards other LLMs

real-time UX-grade latency

how the internet reacted

"I'm guessing it might replace 40-70% of LLM calls for a given pipeline, cutting the API costs on those calls by an order of magnitude."

– HN, 338 pts

"If this holds up, it's going to be huge for game QA work... an LLM can take care of the higher level reasoning then."

– HN on the Doom demo, 450 pts

"But also effectively this is a classification model. It excels at specific workloads, and obviously will fail at others."

– HN skeptic, 384 pts (on TypeSafe's "antibenchmaxxing" post)

press & ecosystem media

- TechCrunch (Sep 18): "Chat6PT broke Diogo Almeida's heart" · Discord town-halls on the Doom demo
- Follow-ups: "antibenchmaxxing", "the bitterest lesson" (typesafe.ai/blog)

GITHUB REPOS · STARS AS OF SEP 19, 2026

The repos, ranked.

official – github.com/typesafe-ai

REPO	STARS	WHAT IT IS
skills	378	agent skills for Claude Code & Codex
typesafe-sdk-js	147	official TypeScript / JS SDK
system-one-adapter-python	134	any big LLM → Jev-shaped decisions
typesafe-sdk-python	101	official Python SDK

community – the flagship wave

REPO	STARS	WHAT JEV DECIDES
browser-use/jev-ultrafast	6,407	click/scroll/type, one call
tamaratran/fast-jev-compaction	3,678	keep/drop per tool call — memory
TheoLeeCJ/SemIf	1,710	semantic ifs on a home 3090
jarrodwatts/jev-trader	984	one trade decision per Monad block
vinnylarouge/jevlike	926	open Jev-like replica + recipe
reticlehq/reticle	729	gate-before-done for agent builds
TianyuCodings/NanoJev	587	nano replica, trained end-to-end
Anil-matcha/awesome-jev-by-typesafe	563	evidence-backed patterns + code
notque/vexjoy-agent	420	/do routing at high frequency
thruwire/foreman	322	foreman for coding-agent fleets
fhshaik/typesafe-mario	270	plays Mario from emulator state

Also: jev-review, awesome-typesafe, jev-mcp, HA-Jev... 134 projects cataloged (stars as of Sep 19, 2026).

Every drop in the cost of intelligence unlocks orders of magnitude more of it.

What's genuinely new: Jev is the first production model whose interface is *decisions instead of language* — a frontier-intelligence function call. It renames the split every agent team eventually discovers: LLMs are System 2 (slow, deliberate, general), Jev is System 1 (fast, typed, calibrated, composable). The ecosystem's verdict is already visible: 5,300+ repos in four days, two flagship projects at 6.4K stars and 3.7K stars, and platform listings on OpenRouter, Venice, Vercel AI Gateway and Cloudflare Workers AI.

What to watch: pricing sustainability ("can't prove it isn't subsidized" — their words), closed weights, single-vendor lock-in, benchmark self-disclosure (evals built by their own capabilities team), and the possibility that big labs simply add calibrated-logprob endpoints to existing chat models — exactly the objection Replit's CEO raised, and the thing to watch in the next two quarters.

```
onvoix verdict
BELIEVE the speed/cost claims — independently felt in production: ~300 ms
batched decisions, output effectively free
BELIEVE the reliability claim directionally: typed outputs + confidence
ladders remove the parse-and-pray layer
DISCOUNT the 193.6×/444.6× headline — use 40–200× as the planning range; treat
"cannot hallucinate" as "cannot invent a type"
ADOPT for triage, routing, scoring, guardrails, compaction, agent gating. Keep
an LLM for reasoning and prose. Escalate at low confidence — that's the whole
design.
```
